## INSTRUCTIONS

MODEL AVR-E4-C FULSE GENERATOR
S.N.:

## WARRANTY

Avtech Electrosystems Ltd. warrants products of its manufacture to be free from defects in material and workmanship under conditions of normal use. If, within one year after delivery to the original owner, and after prepaid return by the original owner, this Avtech product is found to be defective, Avtech shall at its option repair or replace said defective item. This warranty does not apply to units which have been dissembled, modified or subjected to conditions exceeding the applicable specifications or ratings. This warranty is the extent of the obligation or liability assumed by Avtech with respect to this product and no other warranty or guarantee is either expressed or implied.

Fig. 1
PULSE GENERATOR TEST' ARRANGEMENT

1) The bandwidth capability of components and instruments used to display the pulse generator output signal (attenuators, cables, connectors, etc.) should exceed 2 GHz .
2) The use of 60 db attenuator at the scope vertical input channel will insure a peak input signal to the scope of less than one volt (necessary only if sampling scope used). If a high impedance real time scope is used, the pulse generator should be terminated using a shunt 50 ohm resistor.
3) The sync output channel provides TTL level signals. To avoid overdriving the TRIG input channel of some scopes, a 30 db attenuator should be placed at the input to the scope trigger channel. The SYNC output precedes the main output when the front panel LEAD-LAG switch is in the LEAD position. The SYNC output lags the main output when the switch is in the LAG position.
4) To obtain a stable output display the PW and PRF controls on the front panel should be set mid range. The front panel TRIG toggle switch should be in the INT position. The DELAY controls and the scope triggering controls are then adjusted to obtain a stable output. The scope may then be used to set the desired FRF by rotating the PRF controls.
5) The output pulse width is controlled by means of the front panel one turn PW control. To voltage control the pulse width, set the rear panel switch in the EXT position and apply $o$ to +10 volts between terminal $A$ and ground ( $\mathrm{Kin}_{\text {IN }}>10 \mathrm{~K}$ ). (option).
6) The output pulse amplitude is controlled by means of the front panel one turn AMP control. To voltage control the output, set the rear panel switch in the EXT position and apply 0 to +10 volts between terminal $A$ and ground ( $\mathrm{RIN}_{\mathrm{IN}}>1 \mathrm{OK}^{\prime}$ ). (option).
7) An external clock may be used to control the output PRF of the AVR unit by setting the front panel TRIG toggle switch in the EXT position and applying a 0.2 usec (approx.) TTL level pulse to the TRIG BNC connector input. For operation in this mode, the scope time base must also be triggered by the external clock rather than from the SYNC output.
8) For units with the OT offset option, the output DC offset level is varied from -5 to $+5 V$ (to 50 ohm) by the front panel DFFSET one turn control. The DC offset may be turned off using the rear panel $0 S$ ON-DFF toggle switch. (OT option).

(1) ON-OFF Switch. Applies basic prime power to all stages.

PFF Control. Varies PRF as follows:
MIN

| Range 1 | 100 Hz | 1000 Hz |  |
| :--- | :--- | :--- | :--- |
| Range 2 | 1000 Hz | 10 | KHz |
| Range 3 | 10 | KHz | 100 KHz |

The operating PRF should be set using a scope.
(3) DELAY Control. Controls the relative delay between the reference output pulse provided at the TRIG output (4) the main output (5). This delay is variable over the range of 0 to about 1.0 usec. The TRIG output precedes the main output when the LEAD-LAG switch is in the LEAD position and lags when the switch is in the LAG position.
(4) TRIG Dutput. This output is used to trigger the scope time base. The output is a TTL level 100 nsec (approx.) pulse capable of driving a fifty ohm load.
(5) QUT Connector. BNC connector provides output to a fifty ohm load.
(6) PW Control. A one turn control which varies the output pulse width.
(7) AMP Control. A one turn control which varies the output pulse amplitude to a fifty ohm load.
(8) EXT-INT Control. With this toggle switch in the INT position, the FRF of the AVR unit is controlled via an internal clock which in turn is controlled by the PRF controls. With the toggle switch in the EXT position, the AVR unit requires a 0.2 usec TTL level pulse applied at the TRIG input in order to trigger the output stages. In addition, in this mode, the scope time base must be triggered by the external trigger source.

OFFSET. For units with the $D T$ or EO offset option, the output DC offset level is varied from -5 to +5 V (to 50 ohm) by the front panel DFFSET one turn control. The DC offset may be turned off using the rear panel OS ON-OFF toggle switch.

Fig. 3 BACK PANEL CONTROLS

(1) FUSED CONNECTOR, VOLTAGE SELECTOR. The detachable power cord is connected at this point. In addition, the removable cord is adjusted to select the desired input operating voltage. The unit also contains the main power fuse.
(2) O.SA SB. Fuse which protects the output stage if the output duty cycle rating is exceeded.
(3) EA. To voltage control the output amplitude, set the switch in the EXT position and apply 0 to +10 volts between terminal $A$ and ground ( $\mathrm{RIN}_{\mathrm{IN}} \geqslant 10 \mathrm{~K}$ ). (option).
(4) EW. Ta voltage control the output pulse width, set the switch in the EXT position and apply 0 to +10 volts between terminal $A$ and ground ( $\mathrm{Rin}_{\mathrm{N}} \geqslant 10 \mathrm{~K}$ ). (option).
(5) DC DFFSET Input. To DC offset the output pulse, connect a DC power supply set to the desired offset value to these terminals. The maximum allowable DC offset voltage is $\pm 50$ volts, $\pm 200 \mathrm{~mA}$.

Fig. 4

0.5 A

SB

The AVR-E4-C consists of the following basic modules:

1) AVR-E4-PG pulse generator module
2) AVFi-E4-CL clock module
3) +24 V power supply board

The modules are interconnected as shown in Fig. 4. The clock module controls the output PRF and the relative delay between the main output and the SYNC outputs. The FW pulse generator modules generate the output pulse. In the event of an instrument malfunction, it is most likely that the rear panel $0.5 A 5 B$ fuse may have failed due to an output short circuit condition or to a high duty cycle condition.
a) 0.1 usec TTL 1 evel outputs are observed at pins 2 and 3 . b) The FRF of the outputs can be varied over the range of O. 1 KHz to 100 KHz using the PRF \& FRF FINE and FRF RANGE controls.
c) The relative delay between the pin 2 and 3 outputs can be varied by at least 500 nsec by the DELAY controls.

The sealed clack module must be returned to Avtech for repair or replacement if the above conditions are not observed. The power supply board generates $+24 V$ DC to power the other modules. If the voltage is less than +24 V , turn off the prime power and unsalder the lead from the 7824 regulatar chip on the power supply board. Solder a 100 ohm 5 watt resistor to the 7824 output to ground and turn on the prime power. A valtage of +24 valts should be read. If the voltage is less then the power supply board is defective and should be repaired or replaced.
